## 0.1 UNN maths

Our data is generated in the following way:

$$y_{j,t,k}(X) = RBF(X_j)_t + e_{j,k}$$
(1)

 $e_{j,0}, e_{j,1} \sim N(0,2)$  independently.

 $k \in [0,1]$ , j is observation index.

 $X_j = \{x_{j,1}, x_{j,2}, ..., x_{j,N}\}$  with  $x_{j,i} \sim U[5, 15]$  and N being the sequence length.

For simplicity we want to ignore k so that we can talk about the usual 1-D case. Therefore, we create a mapping such that  $y_{j,t,k} - - > y_{j,t}^k$ . And so, for the purposes of log-likelihood, we can proceed as-if k is not there and we have a joint distribution indexed by t. Notice that we do not delete k but just hide it (it is still there).

Our goal is to predict  $P(y_{j,t+1}|y_{j,1},y_{j,2},...y_{j,t})$ .

Since our data is unordered, our dataset might look like:

For maximizing the log-likelihood, we index  $y_{j,i}$  by their respective rows (r) and columns (c).

So  $y_{2,4} - > y_{1,1}$ . Also, given the parameters of the network  $\theta$  the rows of the matrix are conditionally independent. We define a new parameter k such that  $k_j = \{k_{j,1}, k_{j,2}, ..., k_{j,N}\}$ , with

$$k_{r,c} = \begin{cases} 0 & \text{if } y_{r,c} \in k = 0\\ 1 & \text{otherwise} \end{cases}$$
 (2)

For row r, we have (notice that we start from the second column of the matrix our log-likelihood since beforehand we have no history)

0.2. Model 2

$$logP(y_{r,2:N}; \theta, x_{r,1:N}, k_{r,1:N}) = log(P(y_{r,2}|y_{r,1}; \theta, x_{r,1}, x_{r,2}, k_{r,1}, k_{r,2}) \dots P(y_{r,N}|y_{r,1:(N-1)}; \theta, x_{r,1:N}, k_{r,1:N}))$$

$$= \frac{1}{N} \sum_{i=2}^{N} -\frac{1}{2} * \frac{(y_{r,i} - \mu(y_{r,
(3)$$

And for the whole dataset this would be:

$$\sum_{j=1}^{M} log P(y_{j,r,2:N}; \theta, x_{r,1:N}, k_{r,1:N}) =$$
(4)

$$\sum_{j=1}^{M} log(P(y_{j,r,2}|y_{j,r,1};\theta,x_{j,r,1},x_{j,r,2},k_{j,r,1},k_{j,r,2})(y_{j,r,N}|y_{j,r,1:(N-1)};\theta,x_{j,r,1:N},k_{r,1:N}))$$
(5)

$$= \frac{1}{M} \sum_{j=1}^{M} \frac{1}{N} \sum_{i=2}^{N} -\frac{1}{2} * \frac{(y_{j,r,i} - \mu(y_{j,r,\leq i}; \theta, x_{j,r,\leq i}, k_{j,r,\leq i}))^{2}}{\sigma(y_{j,r,< i}; \theta, x_{j,r,\leq i}, k_{j,r,\leq i}))^{2}} - log(\sigma(y_{j,r,< i}; \theta, x_{j,r,\leq i}, k_{j,r,\leq i}))$$
(6)

Where we assume here-under that:

$$y_{i,t}|y_{i,< t};x_{i,< t},k_{i,< t} \sim N(\mu(y_{i,< t};x_{i,< t},k_{i,< t},\theta),\sigma(y_{i,< t};x_{i,< t},k_{i,< t},\theta))$$

And 
$$y_{r,< i} = [y_{r,1}, y_{r,2}, \dots, y_{r,i-1}]$$
 and  $y_{r,2:N} = [y_{r,1}, y_{r,2}, \dots, y_{r,N}]$ 

## 0.2 Model

Predicting target variable  $y_{t+1}$  is calculated by:

First, we embed the x-values, y-values, and k-values (which sequence 0/1).

$$x_{t,j} = embedding(x_t)_j \tag{7}$$

0.2. Model 3

$$y_{t,j} = embedding(y_t)_j \tag{8}$$

$$k_{t,j} = embedding(k_t)_j \tag{9}$$

embedding  $\in R^e$ 

Secondly, we create a dot product attention:

$$Q_{t,j} = \sum_{h=1}^{e} x_{t,h} * wq_{h,j}$$
 (10)

$$K_{t,j} = \sum_{h=1}^{e} x_{t,h} * w k_{h,j}$$
 (11)

$$V_{t,j} = \sum_{h=1}^{e} y_{t,h} * w v_{h,j}$$
 (12)

 $Q_t$  (Query),  $K_t$  (Key),  $V_t$  (Value) ( $\in R^e$ ) and ( $wq, wk, wv \in R^{exe}$ )

The next layer ("MatMul") is defined as:

$$(dot)_{t,m} = \sum_{h=1}^{e} Q_{th} * K_{hm}^{T}$$
 (13)

Where  $dot \in R^{(t+1)x(t+1)}$ , t is the row index embedding of target variable  $y_t$  in Q, and m is the row index embedding of target variable  $y_m$  in K.

The "score" layer is used to normalise the dot layer and is calculated as:

$$score_{j,k} = \frac{exp^{(dot)_{j,k}}}{\sum_{h=1}^{j-1} exp^{(dot)_{j,h}}}$$
(14)

Where j=2:t+1. Notice that score will be a lower triangular matrix (upper = 0).  $score \in R^{txt}$  and t is the index representing the row of similarities between the embedded  $y_t$  and the embedded  $y_k$ , with  $k \le t$ .

The last layer indicates how much attention we should pay to each of the previous embedded (V) variables in the sequence. The output from this layer we call "att".

0.2. Model 4

$$att_{t,j} = \sum_{h=1}^{t} score_{t,k} * V_{k,j}$$
(15)

$$out_{t,j} = \sum_{h=1}^{\ell} att_{t,h} * A1_{h,j} + \sum_{h=1}^{\ell} x_{t+1,h} * A2_{h,j} + \sum_{h=1}^{\ell} k_{t+1,h} * A3_{h,j}$$
 (16)

$$out_{t,j} = max(0.01 * out_{t,j}, out_{t,j})$$

$$(17)$$

$$out_{t,j} = \sum_{h=1}^{\ell} out_{t,h} * A_4 h, j$$
 (18)

A1, A2 and A3  $\in R^{ex\ell}$ , A4  $\in R^{\ell x2}$
